

6 Electric Potentials of Charge Distributions, Equipotentials, Potential Gradient

6.1 Book Notes

- An equipotential surface is a three-dimensional surface on which the electric potential V is the same at every point.
- On a given equipotential surface, the potential V has the same value at every point. In general, however, the electric-field magnitude E is not the same at all points on an equipotential surface.
- When all charges are at rest, the surface of a conductor is always an equipotential surface
- In an electrostatic situation, if a conductor contains a cavity and if no charge is present inside the cavity, then there can be no net charge anywhere on the surface of the cavity.
- surface charge density on the wall of the cavity is zero at every point.
- Don't confuse equipotential surfaces with the Gaussian surfaces we encountered in Chapter 22. Gaussian surfaces have relevance only when we are using Gauss's law, and we can choose any Gaussian surface that's convenient. We cannot choose equipotential surfaces; the shape is determined by the charge distribution.

6.2 Lecture Notes

- The disk of charge will be on exam.
- The "Ed" equation does not require rectangular plates, or any plates at all. It works as long as E is uniform and parallel or antiparallel to d .

6.3 Recitation

- Potential is a scalar, which awesommmmmee.
 - But we can't exploit symmetry because of no directions.
