Last Modified: March 6, 2017

## Problem #1

Suppose  $P$  is a level and  $M$  is a level set. The statement that  $P$  is a **bottom level** of  $M$  means if  $x$  is a level in  $M$  then  $P$  cannot be above  $x$ .

### Class Solution

$P$  is a bottom level of the level set  $M$  if  $P$  is a level in  $M$  so that if  $x$  is a level in  $M$  then  $P$  is not above  $x$ .

## Problem #2

**Theorem 1.** *If  $M$  is a level set having exactly one level,  $M$  **does** a top level.*

*Proof.* Suppose that  $\exists P \in M$ , where  $P$  is a level and  $M$  is a level set. Suppose, also, that  $P$  is the only level in  $M$ . By our definition of **top level**, we state that the **top level** of  $M$  means  $P$  is a level in  $M$  and if  $x$  is a level in  $M$  then  $x$  is not above  $P$ . But we only have one level in  $M$ , that is  $P$ .

Therefore,  $x$  must be  $P$ , and because Axiom 1 (If  $P$  is a level then  $P$  is not above  $P$ ) agrees with our definition  $x$  is not above  $P$ .  $\square$

### Class Solution

Yes, because if level set  $M$  contains a single level  $P$  any level  $x$  within  $M$  would be  $P$  so according to Axiom 1 satisfies the definition of a top level of level set  $M$ .

### Problem #3

With respect to all these definitions, can infer that  $P$  is a bottom level in set  $M$ . One can infer that level  $P$  is a bottom level.

### Problem #4

No.

*Proof.* Suppose not. That is, suppose there exists levels  $P, Q, x$  in the level set  $M$ , where  $P$  is a different name for  $Q$ . Because they are both representations of each other, we will write  $Q$  to represent both  $P$  and  $Q$ .

Rewriting Axiom 2 in this notation, it states as follows:

If each of  $Q$  and  $Q$  is a level and  $Q$  is above  $Q$  then there exists a level  $x$  such that  $Q$  is above  $x$  and  $x$  is above  $Q$ .

This argument is no longer valid, because it builds on the premise that  $Q$  is above  $Q$  (by Axiom 1, this not valid). This is a violation of Axiom 1.  $\square$

### Problem #5

If  $P$  and  $Q$  are levels then  $P$  is above  $Q$  and  $Q$  is above  $P$ , then (by Axiom 3) this implies that  $P$  is transitive above  $P$ , which by Axiom 1 is a contradiction.

### Class Solution (Osman)

No, if  $P$  and  $Q$  are levels such that  $P$  is above  $Q$  and  $Q$  is above  $P$ , then by Axiom 4 the  $P$  is above  $P$  which violates Axiom 1.

### Problem #6

No.

*Proof.* Suppose not. That is, suppose that there exists two, different levels  $P, Q$  in the level set  $M$ . By Axiom 3,  $P$  is above  $Q$  or  $Q$  is above  $P$ , but not both (because that would imply  $P$  is above  $P$ ). By our definition of top level,

$P$  and  $Q$  must be a top level if  $\exists x \in M$ , where  $x$  is not above  $P$  and  $Q$ , but by Axiom 2  $\exists x \in M$  such that  $P$  is above  $x$  and  $x$  is above  $Q$ . Because the statements  $x$  is above and  $P, Q$  and  $P$  is above  $x$  and  $x$  is above  $Q$  cannot both hold, this is a contradiction.  $\square$

### **Class Solution (Matthew Kovar)**

*Proof.* If  $P$  and  $Q$  are both top levels in a level set  $M$ , then there is no level  $x$  in the level set  $M$  above  $P$  or  $Q$  (by Definition 1), which means that  $P$  cannot be above  $Q$  and  $Q$  cannot be above  $P$ . However, this violates Axiom 3 which states that  $P$  must be above  $Q$  or  $Q$  must be above  $P$ . Therefore, there cannot be more than one top level in a level set.  $\square$

## **Problem #7**

The following answer is wrong. An empty level set is simply an empty set, not an empty level set.

- (a) A level set that satisfies the property of having no top level is the empty set,  $\emptyset$ .
- (b) The empty set  $\emptyset$  also satisfies this property.
- (c) Assume  $\exists P \in M$ , where  $P$  is an arbitrary level and  $M$  to be the level set of all levels. Therefore, there are is no top level (if  $Q \in M$ , if  $Q$  is said to be the top level,  $\exists x \in M$ , where  $x$  is above  $Q$ ), but  $P$  such that if  $x \in M$  then  $P$  is above  $x$ .

### **Class Solution (Brett Sears, Illya Starikov, Matthew Healy)**

- (a) (Brett Sears) Let  $M$  be a level set containing some level  $P$ . A level  $x$  is included in  $M$  if  $x$  is above  $P$ . Suppose  $T$  is the top level of  $M$ . By Axiom 5, we know there is also a level  $U$  above  $T$ ,  $T$  is above  $P$  or  $P$ . By Axiom 4,  $U$  is above  $P$  and included in  $M$ . Therefore there is no level that satisfies the definition of of a top level, and this is a contradiction.

- (a) (Illya Starikov) Suppose  $M$  to be the level set of all levels. By our definition of top level, there exists a top level in  $M$  if there is a level  $x, P \in M$ , then  $x$  is not above  $P$  (where  $P$  is to be the candidate top level). However, for every level  $P$ , there is a level  $x$  above it.  $\therefore M$  has no top level.
- (b) (Matthew Healy) Suppose  $M$  to be the level set of all levels. For any bottom level  $b$  which we have defined a level such that for any level  $x \in M$ ,  $b$  is not above  $x$ . By Axiom 5, there exists level  $x$  and  $y$ , such that  $y > b > x$ . Since this causes  $b$  to be above another level  $x \in M$ ,  $b$  no longer satisfies the definition of a bottom level.
- (c) (Brett Sears) Let  $M$  be the level set that includes every level  $P$  is above, but does not include  $P$ . Let  $T$  be a potential top level for  $M$ . By Axiom 2, there is a level  $x$  such that  $P$  is above  $x$ ,  $x$  is above  $T$ . Since  $P$  is above  $x$ ,  $x$  must be included in the level set  $M$ . However, since  $x$  is above  $T$ , the definition of a top level is not satisfied. So  $M$  does not have a definitive top level.

## Problem #8

### Class Solution

Let level set  $S_1$  have a top level  $Q$ . Under the hypothesis of Axiom 6, suppose level set  $S_2$  has a bottom level  $P$ . By Axiom 2, there exists a level  $x$  such that  $P$  is above  $x$  and  $x$  is above  $Q$ . Since  $x$  must be in  $S_1$  or  $S_2$  under the hypothesis of Axiom 6 and since  $Q$  is the top level of  $S_1$ , then  $x$  must be in  $S_2$ . Since bottom level  $P$  in  $S_2$  is above level  $x$  in  $S_2$ , Kyle Foster's definition of a bottom level is violated and level  $P$  cannot be a bottom level. Therefore, if  $S_1$  has a top level,  $S_2$  cannot have a bottom level.

## Problem #9

The level  $P$  is not the top level of the level set  $M$  means ... *there is more than one level in  $M$ .*

## Class Solution (Terry Maxwell)

The level  $P$  is not the top level of the level set  $M$  means ... *the level  $P$  may or may not be included in the level set  $M$  and if  $P$  is included in  $M$  then there must exist a level  $x$  in level set  $M$  and  $x$  must be above  $P$ .*

## Theorem #1

**Theorem 2.** *If  $M$  is a level set and a level  $B$  is above every level of  $M$  then  $M$  has a top level or there is a bottom level of the level set of all the levels that are above every level in  $M$ .*

*Proof.* Let  $C$  be the level set of all levels above every level above  $M$ , and let  $D$  be the level set of all levels not in  $C$ .

Any level  $x$  must be in either level set  $C$  or level set  $D$ . Assume there is a level  $y$  in  $C$  such that  $y$  is not above a level  $z$  in  $D$ . If  $y$  is  $z$ , then this would imply  $y$  is in both level set  $C$  and  $D$ , which is a contradiction. If  $y$  is not above  $z$  and not  $z$ , then,  $z$  is above  $y$ . Since  $y$  is above every level in  $M$ , then, since the hypothesis of Axiom 4 is satisfied,  $z$  would be above every level in  $M$ , which implies  $z$  is in both set  $C$  and set  $D$ , contradicting sets  $C$  and  $D$ 's definitions. Since every level in level set  $C$  is above every level in level set  $D$ , the hypothesis of Axiom 6 is satisfied. Therefore, through the conclusion of Axiom 6, level set  $D$  has a top level or level set  $C$  has a bottom level.

But does this satisfy the original hypothesis of Theorem 1?

Yes, since level set  $D$  is also a level set, and a level  $B$  is above every level of  $M$  and, by our definition of  $C$ ,  $B$  is in set  $C$ .

Claim: Level set  $D$  and level set  $M$  must both have a top level or both not have a top level.

Bare denial of the claim: Suppose level set  $D$  does not have a top level and level set  $M$  does, or level set  $D$  does have a top level and level set  $M$  does not.

**Case #1**  $D$  does not have a top level and  $M$  does, and  $D$  does have a top level and level set  $M$  does not. A level set, by our definition of top level, cannot have both a top level and no top level at the same time.

**Case #2**  $D$  does have a top level  $T$  and  $M$  does not.

By our definition of level set  $D$ , level set  $M$  does not contain levels that are above any levels in level set  $D$ . Yet, level set  $D$  also contains all of

the levels within level set  $M$ , since the level set  $M$  is not included in level set  $C$ . So, if  $D$  does have a top level, then, because

1.  $M$  does not have any levels that are above the levels in  $D$ .
2.  $D$  contains all levels of  $M$ .
3.  $D$  does not contain any levels that are above all levels in  $M$ .

We have already shown  $C = \{\text{all levels above every level in } M\}$ ,  $D = \{\text{every level not in } C\}$ , and Axiom 6 to be satisfied. If  $T$  is below  $\forall x \in C$  then  $\forall x \in M$  not above  $T$  and  $T \notin C \implies T \in M$  or  $Q \in M$  above  $T$ .

This must be true because there is no level  $Q$  in  $M$  that can satisfy being above  $T$  because it must then be a member of  $D$  and violate the definition of top level held by  $T$ , forcing  $Q$  to be in  $C$ . Therefore  $T \in M$  and thus the top level of  $M$ .

**Case #3**  $M$  does have a top level  $T$  and  $D$  does not. In this instance, see Case 2. If  $M$  has a top level, then  $D$  must include that top level  $T$  and no levels above  $T$ .

Therefore, since our bare denial has been proven false, our claim must be true!  $\square$

## Problem #10

Suppose  $P$  and  $Q$  are levels. To say that  $P$  is **below**  $Q$  is to say that  $Q$  is above  $P$ .

**Conjecture 1.** *If  $P$  is a level then  $P$  is not below  $P$ .*

*Proof.* Suppose there is a level  $P$  such that  $P$  is below  $P$ . By the definition of below this says  $P$  is above  $P$ . This contradicts Axiom 1. Thus there is no level which is below itself.  $\square$

## The Bare Denial of Above

The bare denial of  $P$  is above  $Q$  is  $P$  is below  $Q$  or  $P$  is  $Q$ .

## Problem #11

### Class Solution

A level  $P$  is an accumulation level of the level set  $M$  if a segment  $s$  contains  $P$  then  $s$  also contains a level of  $M$  distinct from  $P$ .

## Problem #12

### Class Solution (Terry Maxwell)

A level  $P$  is not an accumulation level of level set  $M$  if  $P$  is contained in a segment  $s$ , and there are no levels in  $s$  that are contained in level set  $M$  other than  $P$ .

## Problem #13

### Class Solution

1. (Daniel Welker)  $M$  is the level set containing only the level  $A$ . By Axiom 5, there must exist levels  $x$  and  $y$  such that  $y$  is above  $A$  and  $x$  is below  $A$ . These levels  $x$  and  $y$  may not be in the level set  $M$  because we have defined the level set  $M$  to contain only the level  $A$ . The levels  $x$  and  $y$  may form a segment  $s(x, y)$  which contains the level  $A$  in level set  $M$ . Since there are no distinct levels of  $M$  in  $s(x, y)$  other than  $A$ , the bare denial of the definition of an accumulation level is satisfied so that  $A$  is not an accumulation level of  $M$ .
2. (Daniel Welker) Suppose  $B$  to be above  $A$  such that  $y > B > A > x$ . Then  $B$  would be in segment  $s(x, y)$ . The segment  $s$  contains levels  $A$  and  $B$ , but only  $A$  is a member of level set  $M$ . Then  $s(x, y)$  is not an accumulation level of  $M$  because it does not contain a level of  $M$  distinct from  $A$ .

## Problem #14

### Class Solution (Elisabeth Warner)

By Axiom 5, there exists levels  $x$  and  $y$  such that  $y$  is above  $A$  and  $A$  is above  $x$ . There also exists levels  $z$  and  $w$  such that  $z$  is above  $B$  and  $B$  is above  $w$ . However, because  $M$  is the level set that only contains  $A$  and  $B$ , levels  $x$ ,  $y$ ,  $z$ , and  $w$  are not in  $M$ .

In order for  $B$  (or  $A$ ) to be an accumulation level of  $M$ , every segment  $s$  containing  $B$  (or  $A$ ) must also contain a level of  $M$  distinct from  $B$  (or  $A$ ).

**Take  $A$  to be above  $B$**  If  $A$  is above  $B$  and  $y$  is above  $A$ , then  $y$  is above  $B$  (Axiom 4). Take segment  $s(w, y)$ .  $B$  is above  $w$  but below  $y$ , so  $B$  is in the segment.  $A$  is above  $B$  (and thus above  $w$ ) and  $y$  is above  $A$ , thus  $A$  is also in  $s$ .  $B$  is a possible accumulation level of  $M$  because segment  $s(w, y)$  contains  $A$  (a level in  $M$  distinct from  $B$ ).

However, take segment  $s(w, A)$ . As  $B$  is below  $A$ ,  $B$  is included in  $s$ , but the level  $A$  is not included in the segment  $s(w, A)$ , by the definition of a segment. There is not a level in  $s(w, A)$  of  $M$  distinct from  $B$ , therefore  $B$  is not an accumulation level of  $M$ .

Nevertheless,  $A$  could be an accumulation level of  $M$ . Take segment  $s(B, y)$ .  $A$  is above  $B$  and  $y$  is above  $A$ , so  $A$  is in segment  $s$ . However,  $B$  is not in segment  $s$  (endpoints not in segments), therefore there  $s(B, y)$  does not contain  $B$  (a level in  $M$  distinct from  $A$ ), thus  $A$  is not an accumulation level of  $M$ .

Suppose  $y$  is an accumulation of  $M$ . By Axiom 5, there exist levels  $j$  and  $k$ , where  $j$  is above  $y$  and  $y$  is above  $k$ . Take segment  $s(A, j)$ . Level  $y$  is in the segment due to the fact that  $y$  is above  $A$  but below  $j$ . Segment  $s$  does not contain either  $A$  or  $B$ , thus it does not contain a level in  $M$  distinct from  $y$ . Therefore,  $y$  is not an accumulation level of  $M$ .

**Take  $B$  to be above  $A$**   $B$  is above  $A$  and  $z$  is above  $B$ , thus  $z$  is above  $A$ . Take segment  $s(x, z)$ .  $A$  is above  $x$  and  $z$  is above  $A$ , thus  $A$  is in the segment.  $B$  is above  $A$  but below  $z$ , so  $B$  is also in segment  $s$ . Segment  $s(x, z)$  contains a level in  $M$  distinct from  $A$ , thus  $A$  is an accumulation level of  $M$ .

Take segment  $s(x, B)$ .  $A$  is in  $s$ , as  $A$  is below  $B$ , but  $B$  is not in  $s$ . Segment  $s(x, B)$  does not contain a level in  $M$  distinct from  $A$ , thus  $A$  is not an accumulation level of  $M$ .

Testing  $B$ : take segment  $s(A, z)$ .  $B$  is in  $s$  ( $B$  is above  $A$  but below  $z$ ), but  $A$  is not in  $s$  (endpoints of a segment). Therefore, segment  $s(A, z)$  does not contain  $A$  (a level in  $M$  distinct from  $B$ ), thus  $B$  is not an accumulation level of  $M$ .

There is not any level that satisfies the qualifications to be an accumulation level of level set  $M$ .

## Problem #15

### Class Solution (Brett Sears)

Yep.

Suppose there were no level  $x$  such that  $x$  is an accumulation level of  $s$ . In other words, suppose it were possible to define a segment  $q(z, y)$ , such that  $x$  is included in  $q$  with no other levels also in  $s$  distinct from  $x$ .

Let  $x$  be a level between  $(A, B)$ .

If  $z$  is between  $(A, B)$  and  $y$  is above  $B$ . Then, there must be a level  $x$  between  $z$  and  $B$  (Axiom 2). Then, there must also be another level  $R$  between  $z$  and  $x$ . Since  $R$  and  $x$  are both between  $z$  and  $y$  and both included within  $(A, B)$ ,  $(z, y)$  must contain a level distinct from  $x$  that is also included in  $(A, B)$ .

If  $z$  is between  $A$  and  $B$  and  $y$  is between  $A$  and  $B$ . Then, there must be a level  $x$  between  $z$  and  $y$  (Axiom 2). Then, there must also be another level  $P$  between  $z$  and  $x$  (Axiom 2). Since  $B$  is above  $x$  is above  $z$ , and  $x$  is above  $z$  is above  $A$ ,  $B$  is above  $x$  is above  $A$  (Axiom 4), which means  $x$  is between  $A$  and  $B$  and thus included on  $(A, B)$ . A similar argument can be made for level  $P$ . However,  $P$  and  $x$  are both included in  $(z, y)$ , so  $(z, y)$  must contain a level distinct from  $x$ .

If  $z$  is below  $A$  and  $y$  is between  $A$  and  $B$ . Then, there must be a level  $x$  between  $y$  and  $A$  (Axiom 2). Likewise, there must also be another level  $R$  between  $x$  and  $y(x, y)$ .

If  $z$  is below  $A$  and  $y$  is below  $A$ . Suppose  $x$  is included in  $(z, y)$ . Then,  $x$  is between  $z$  and  $y$ ; in other words,  $y$  is above  $x$  is above  $z$ . However,  $x$

is also included in  $(A, B)$ .  $x$  must be above  $A$  since  $x$  is between  $A$  and  $B$ . So,  $x$  must be above  $A$  must be above  $y$ . However,  $y$  is above  $x$ , leading to a contradiction.

If  $z$  is above  $B$  and  $y$  is above  $B$ . Suppose  $x$  is included in  $(z, y)$ . Then,  $x$  is between  $z$  and  $y$ ; in other words,  $y$  is above  $x$  is above  $z$ . However,  $x$  is also included in  $(A, B)$ .  $x$  must be above  $A$  since  $x$  is between  $A$  and  $B$ . So,  $x$  is above  $z$  is above  $B$ . However,  $B$  is above  $x$ , and by Axiom 4 we would have  $x$  is above  $x$ , leading to a contradiction.

If  $z$  is  $A$  and  $y$  is  $B$ . Then any level between  $z$  and  $y$  is also included in  $(A, B)$ .

All possible segments have been exhausted.
